

DevTools Implementation Summary

In this project, I used Chrome DevTools to analyze, debug, and improve my web application.

First, I implemented different types of console logging including `console.log()`, `console.info()`, `console.warn()`, and `console.error()`. These logs helped display important information about the program's behavior and made it easier to track what was happening during execution. I also used `console.table()` to organize data in a readable format and `console.group()` to group related logs together.

Next, I explored the Network tab and created a 404 error by referencing a missing file. This demonstrated how DevTools can be used to identify broken links or missing resources in a web application.

I also used the Console filtering feature to search and filter specific messages by text and log level. This made it easier to focus on relevant logs and ignore unnecessary output.

For debugging, I used breakpoints and the debugger statement in the Sources tab. This allowed me to pause the execution of my code and inspect how it runs step-by-step. While paused, I examined variable values using the Scope panel and added expressions to the Watch panel, such as `pet_info.weight`, to monitor changes in real time.

Finally, I reproduced and analyzed a `TypeError` caused by attempting to access a property of a null object. I explained how this error can be fixed by checking if the object exists before accessing its properties.

Overall, Chrome DevTools helped me better understand how my program executes, identify errors, and debug issues more effectively.
